TrolleyCheck Pilot — Executive Build Summary

TrolleyCheck

From a single prompt to a fully deployed, tested, production-ready application.

The Starting Point — One Prompt

The entire project began with a single instruction handed to Claude Code:

> "*Hand this to Claude Code to begin building. Every decision is documented. Every story has acceptance criteria.*"

That instruction was attached to `SPEC.md` — a 600-line product specification written before a single line of code existed. It defined the problem, the stack, the user stories, the data model, the API contract, the CI/CD pipeline, the security rules, and the Azure migration path. Claude Code was given the spec and told to build story by story, raise a GitHub issue per story, branch from `develop`, and not proceed to the next story until the previous one was reviewed.

No scaffolding. No starter kit. Just a spec and Claude Code.

What TrolleyCheck Does

Australians overspend on groceries because prices vary significantly between Coles, Woolworths, IGA and ALDI — but comparing them manually takes time. TrolleyCheck solves this in three steps.

Step 1 — Build your weekly list

The user opens the app and creates a grocery list for the week. They can:

- Search the product catalogue (90+ items across 9 categories — Dairy, Bread, Meat, Produce, Pantry, Drinks, Household, Cleaning, Confectionery)
- See live prices from all 4 stores on every product before adding
- Add products with one tap, or type a custom item not in the catalogue
- Set quantity and unit for each item
- Tick items off as they shop

The app remembers their list week to week and carries over any unticked items automatically.

Step 2 — Compare the full basket

With one tap on **Compare prices**, the app sends the full list to the API, which:

1. Looks up the current price of every item at Coles and Woolworths
2. Calculates the total cost at each store
3. Identifies which store is cheaper overall and by how much
4. Returns an item-level breakdown sorted by saving

The result screen shows the total at both stores, the saving amount highlighted in green, and a colour-coded breakdown of every item with its price at each supermarket.

Step 3 — Split shop for maximum saving

The **Split Shop** feature goes further. Instead of saying "go to Woolworths", it asks: *what if you split your shop between both stores?*

The optimiser calculates:

- Which items are cheaper at Coles → buy those at Coles
- Which items are cheaper at Woolworths → buy those at Woolworths
- Whether the combined saving crosses the user's minimum threshold (configurable: $2 / $5 / $10 / $15)

- The combined saving vs. doing the full shop at one store

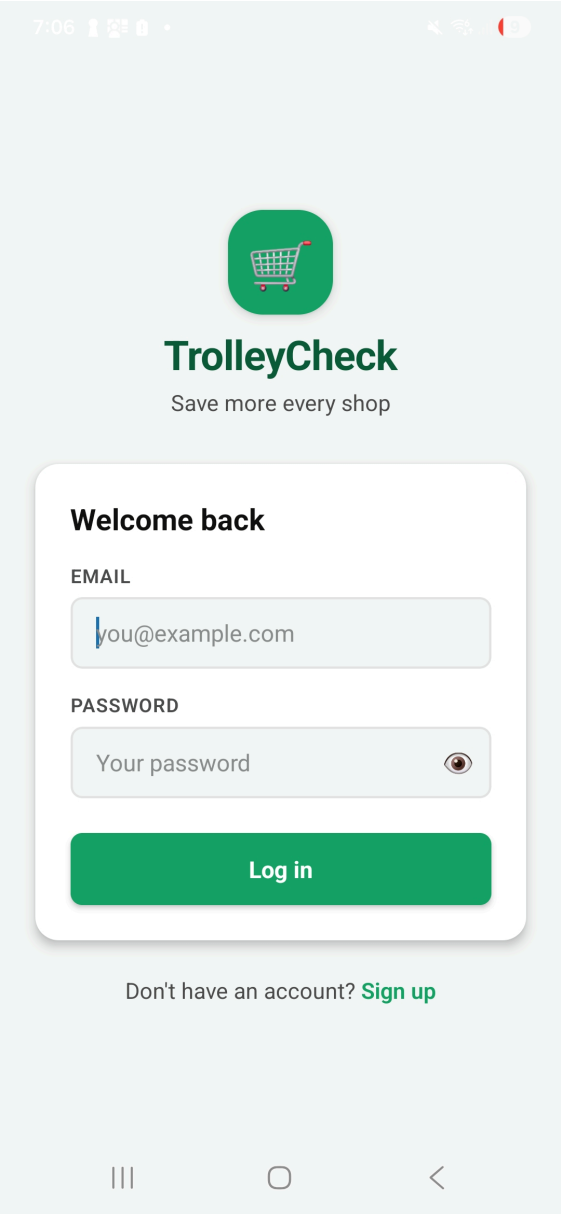
The result is two separate lists — one per store — with the total for each. Users can share either list directly from the app.

Dashboard — savings over time

The Dashboard shows the user's savings history across past weeks with spend and savings charts, helping them understand their spending patterns and reinforce the habit of comparing before they shop.

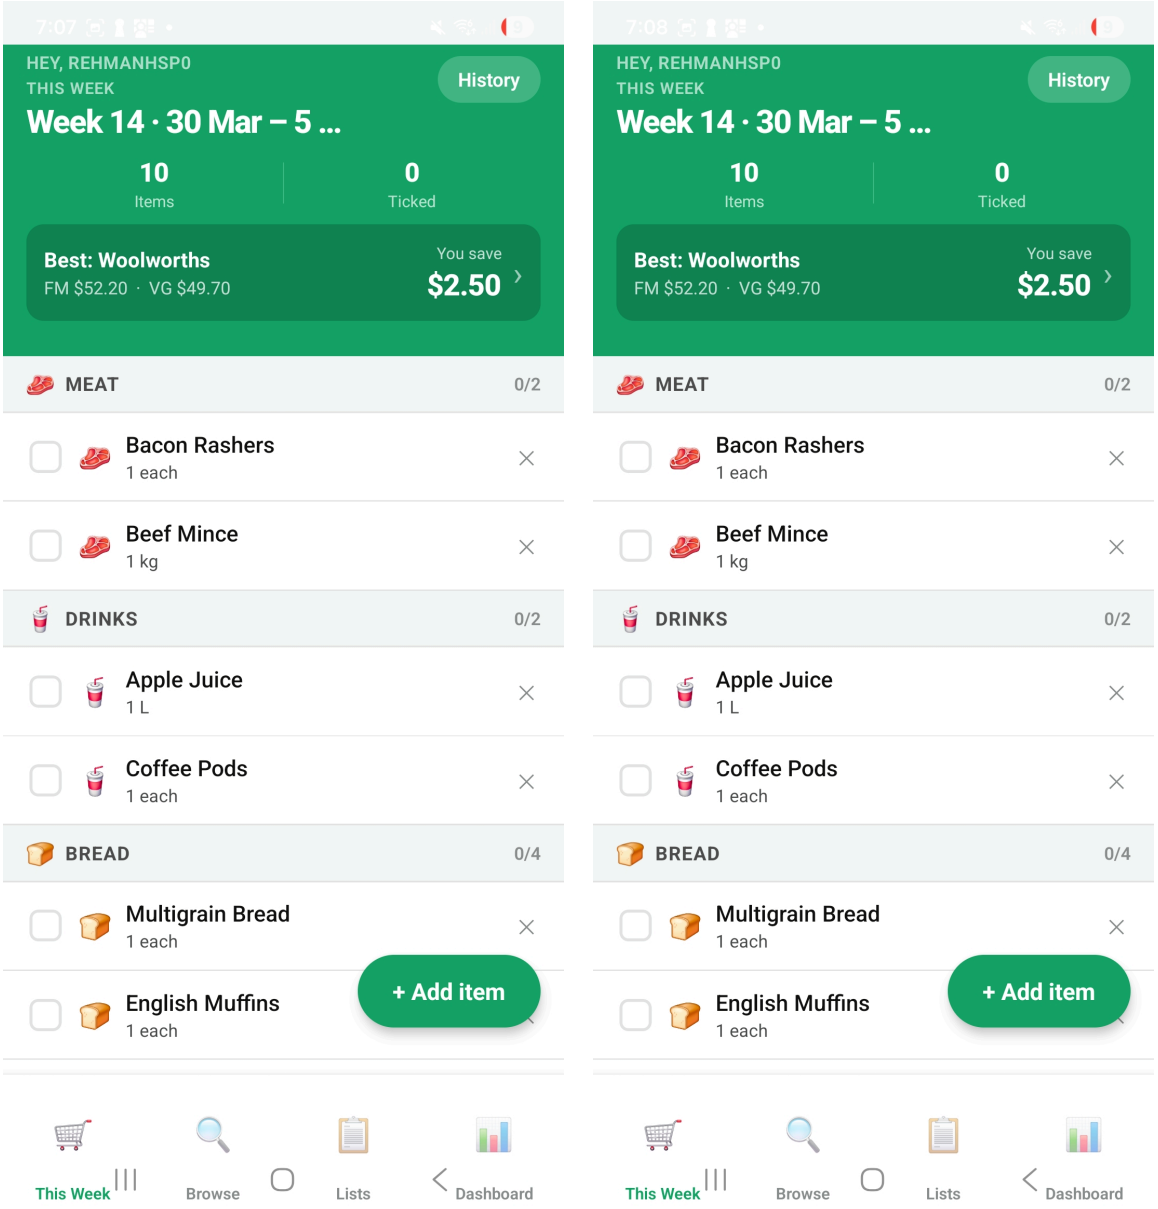
The App — Screenshots

Login



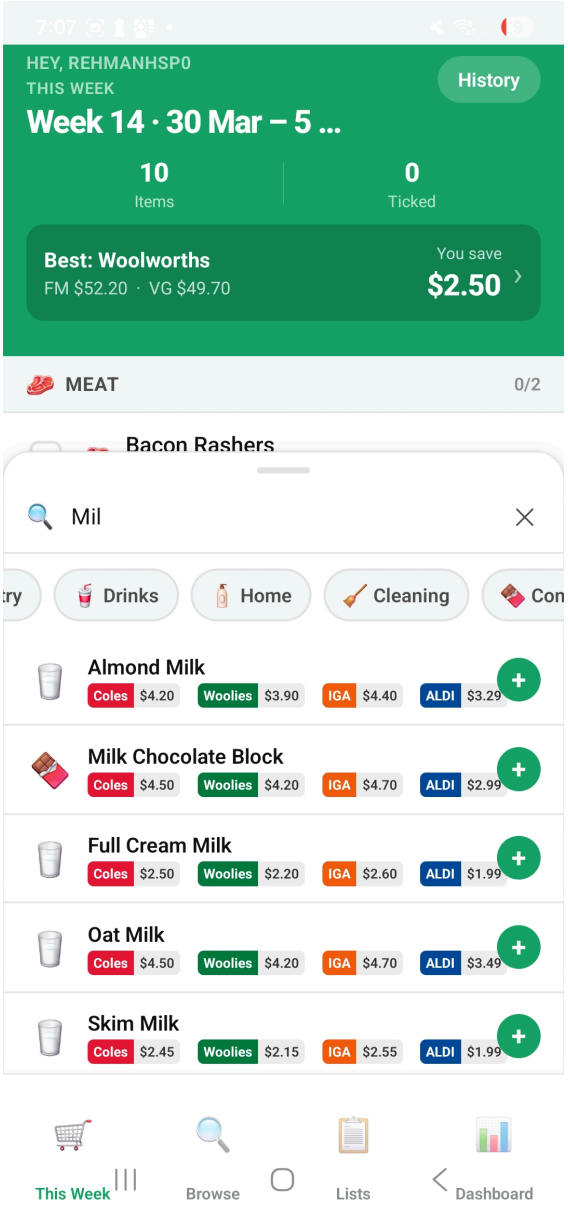
Clean login screen with the TrolleyCheck brand. Email and password authentication via Supabase JWT.

This Week — Weekly Shopping List



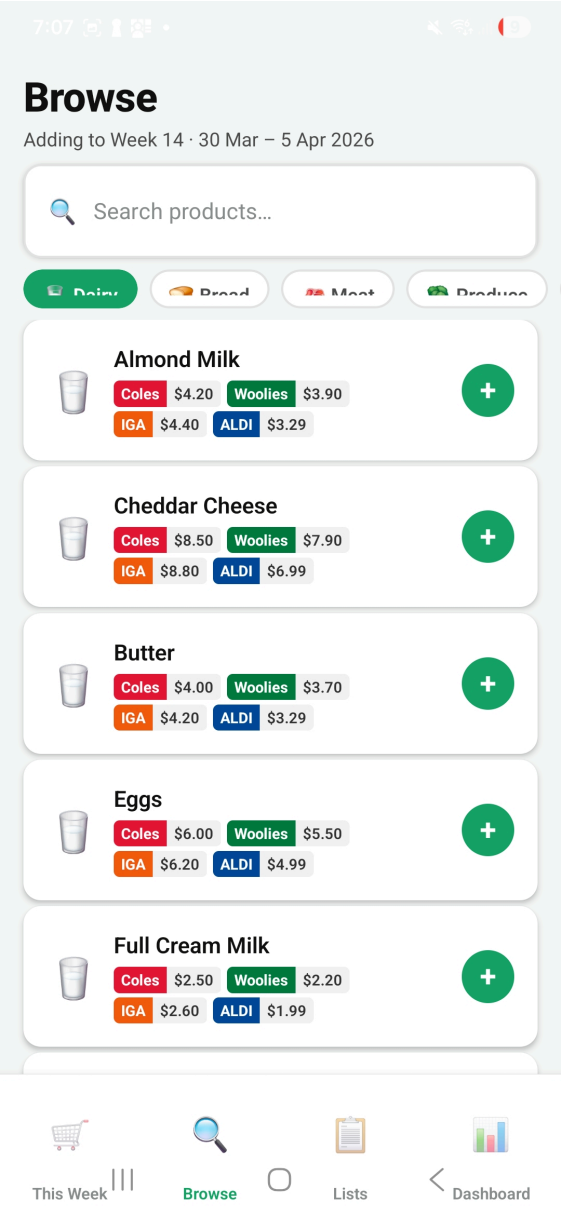
The weekly list groups items by category with tick-off checkboxes. The green header shows the personalised greeting, week number, item count, and the current best-store recommendation with savings — updated live as items are added.

Add Item — Live Product Search with All 4 Store Prices



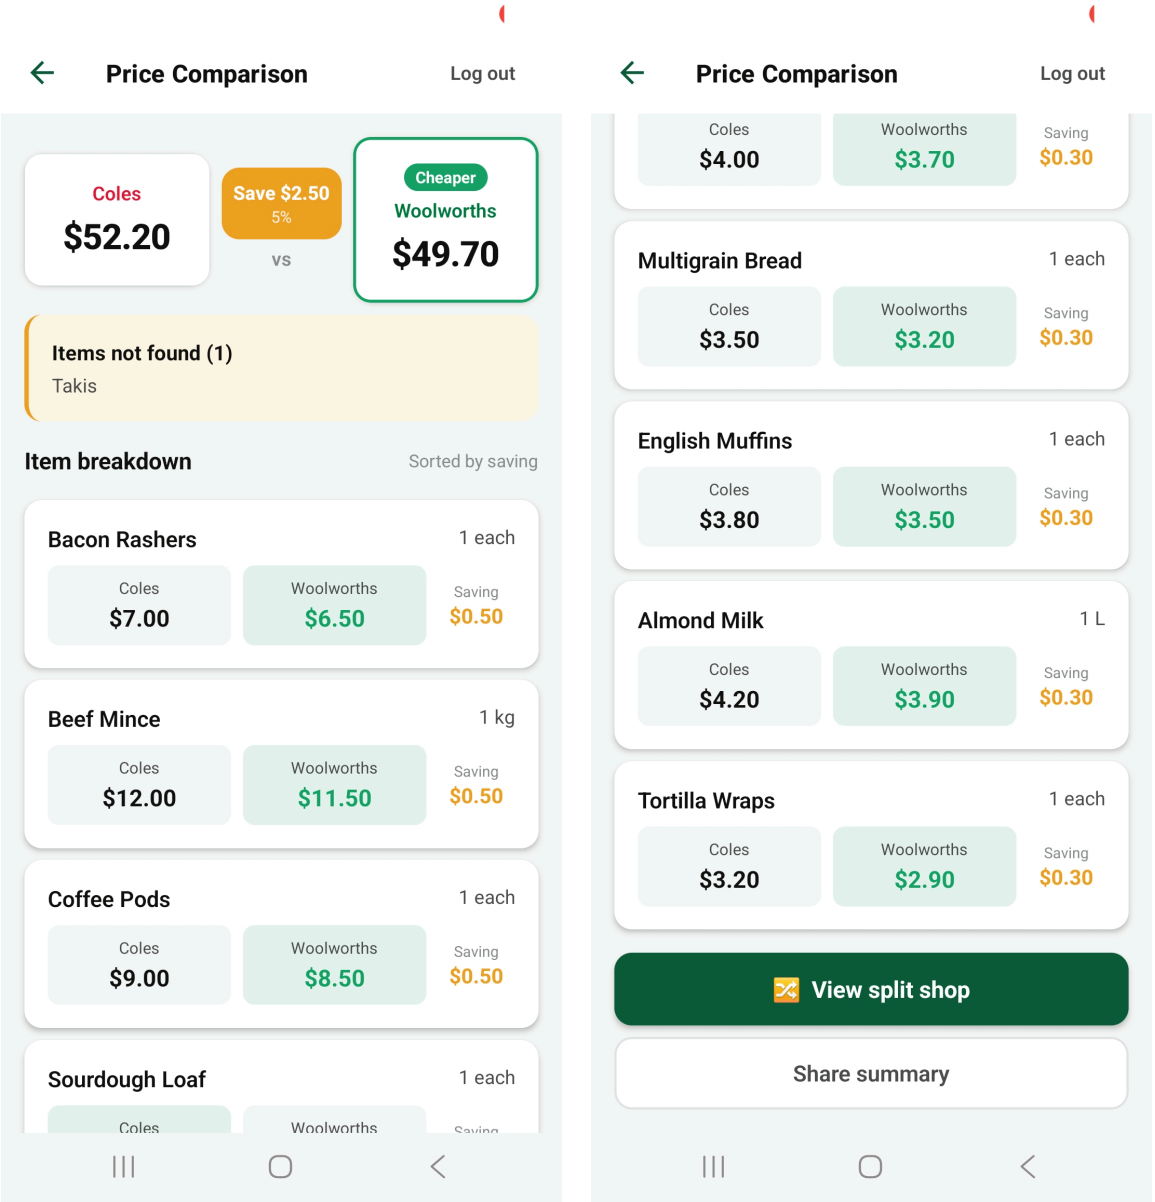
Searching "Mil" returns matching products instantly. Each result shows colour-coded price badges for all four stores — Coles (red), Woolworths (green), IGA (orange), ALDI (blue) — so users know the best price before they even add the item.

Browse — Product Catalogue



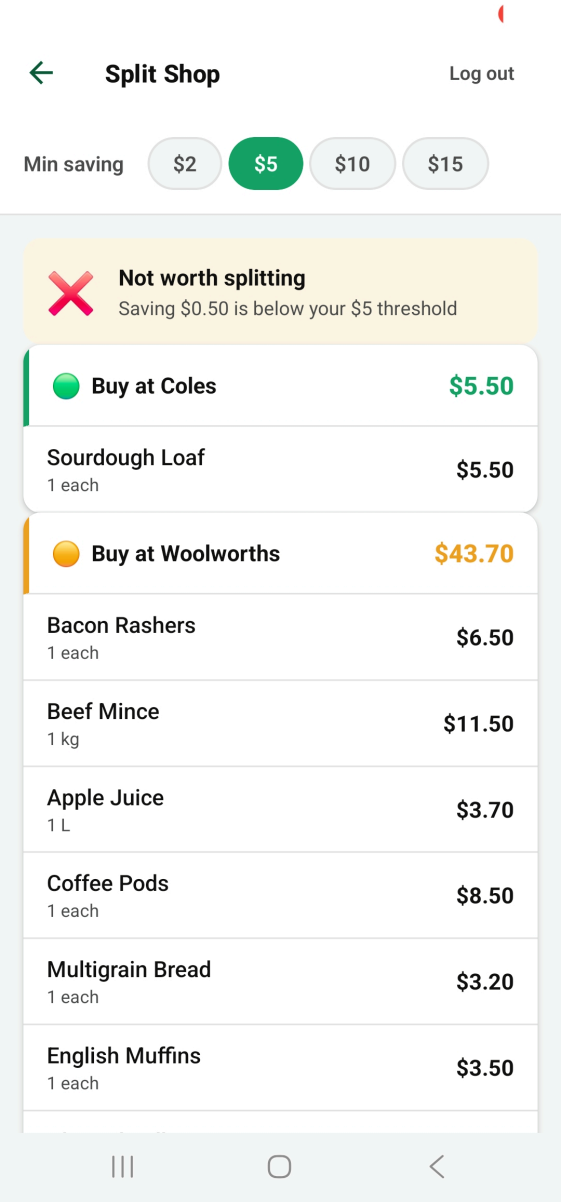
The Browse tab lets users explore 90+ products across 9 categories. Every product shows prices at all 4 stores with brand-coloured badges. One tap adds to the current weekly list.

Price Comparison



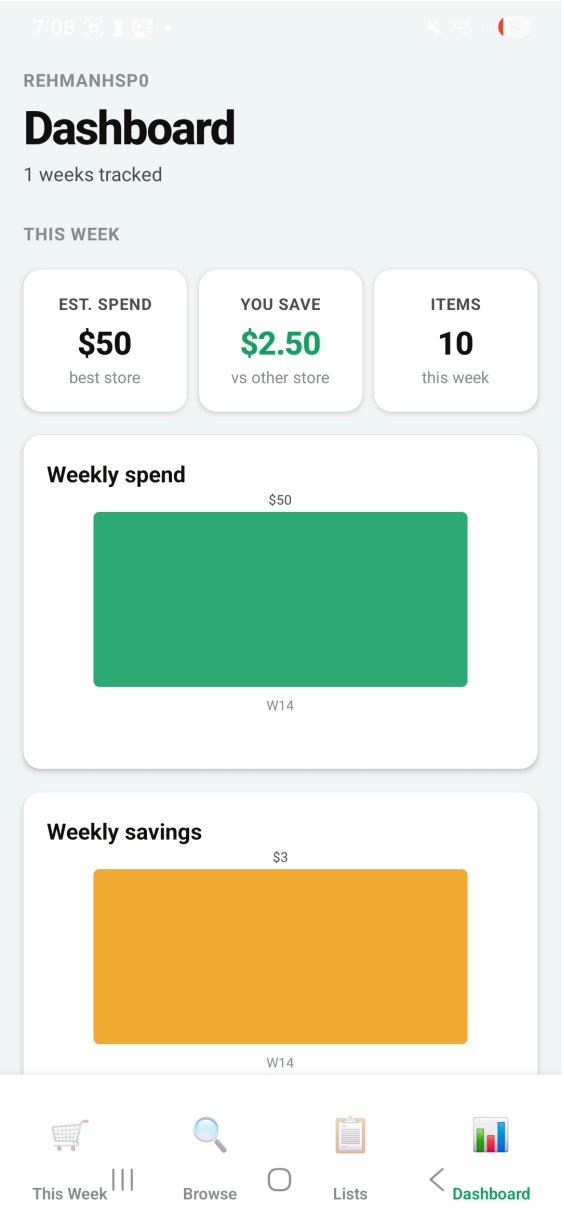
The comparison screen shows the full basket total at Coles and Woolworths side by side, with the cheaper store highlighted in green. Below, every item is listed with its price at each store and the saving — sorted by biggest saving first. Items not found in the catalogue are flagged. The "View split shop" and "Share summary" buttons appear at the bottom.

Split Shop Optimiser



The split shop screen lets users set a minimum saving threshold ($2 / $5 / $10 / $15). If the saving doesn't cross the threshold, the app tells them it's not worth splitting. When it is, items are split into two lists — one per store — with the subtotal for each. In this example: 1 item at Coles ($5.50) and 8 items at Woolworths ($43.70).

Dashboard



The dashboard shows estimated spend ($50), saving vs the other store ($2.50), item count (10), and bar charts for weekly spend and weekly savings — building a picture of habits over time.

What Was Built

Stores supported (pilot)

Store	Brand colour
Coles	Red `#E31837`
Woolworths	Green `#007B40`
IGA	Orange `#EF5A0E`
ALDI	Blue `#004A97`

Screens delivered

Screen	Purpose
Login / Register	Supabase Auth JWT flow
This Week	Weekly shopping list with automatic carry-over
Browse	Search 90+ products across 9 categories
My Lists	Create, manage and delete grocery lists
List Detail	Add items, tick off, see item counts
Price Comparison	Full basket total — Coles vs Woolworths
Split Shop	Per-item store routing for maximum saving
Dashboard	Savings history and spend trends

The Stack

Layer	Technology	Detail
API language	TypeScript (strict mode)	Zero `any`, full type safety
API framework	Express v5	REST — 25+ endpoints
ORM	Prisma v7	All DB access via Prisma only — no raw SQL
Database	Supabase PostgreSQL	Sydney region, row-level security
Auth	Supabase JWT	15 min access tokens / 7 day refresh
Cache	Upstash Redis	6hr TTL on price data
Validation	Zod	Every request body and query param
Logging	pino	Structured JSON, zero PII
Mobile	React Native + Expo SDK 54	iOS + Android
State management	Zustand + React Query	Optimistic updates, caching
Containerisation	Docker (Node 20 Alpine)	Multi-stage build, minimal image
Orchestration	docker-compose	Local dev — API + DB + Redis
CI/CD	GitHub Actions	Lint → Test → Audit → Docker build
Hosting	Railway (Sydney)	Auto-deploy from main
IaC	Terraform	Railway + Azure Container Apps drafted

SDLC — How It Was Run

Every story followed the same flow without exception:

```
SPEC.md story
    │
    ▼
GitHub Issue raised (TC-n)
    │
```

```
    ▼
feature/TC-n-description branch from develop
    │
    ▼
Claude Code implements + TypeScript check + tests pass
    │
    ▼
PR → develop → CI pipeline runs
    │
    ▼
Reviewed and merged
    │
    ▼
Release PR: develop → main → Railway auto-deploys
```

GitHub Issues across the build

#	Story / Bug	Type	Status
TC-1	User registration	Story	Closed
TC-2	User login	Story	Closed
TC-3	Token refresh	Story	Closed

TC-10	Item-level price breakdown	Story	Closed
TC-11	Split-shop optimiser	Story	Closed
TC-12	Product catalogue + seed data	Story	Closed
TC-13	Dockerfile + docker-compose	Story	Closed
TC-14	GitHub Actions CI/CD	Story	Closed
TC-15	React Native mobile app	Story	Closed
#44	CI failing after store rename	Bug	Closed
#45	Delete button not working on web	Bug	Closed
#46	Tab bar disappears in list detail	Bug	Closed
#47	Keyboard overlaps add-item panel	Bug	Closed
#48	Tab bar overlaps Android gesture bar	Bug	Closed

Total commits: 62 | **Merge commits:** 15 | **Branches used:** 18

Security — Built In, Not Bolted On

Security was mandated in the spec as non-negotiable. Every rule was implemented and enforced by CI.

Control	Implementation
Authentication	Supabase JWT — every API route protected
Token lifecycle	15 min access tokens, 7 day refresh, full revocation on logout
Input validation	Zod schemas on every request body and query param
Row-level security	All DB queries scoped to `userId` — users cannot see each other's data
No PII in logs	pino logger — user IDs only, never email or names
Rate limiting	Applied to all endpoints
Dependency audit	`npm audit --audit-level=high` runs on every CI build
Secrets management	Zero hardcoded values — all config via environment variables
SQL injection	Impossible — Prisma ORM only, no raw queries
CORS	Configured explicitly — no wildcard origins in production
Container	Node 20 Alpine — minimal attack surface
Azure-ready	All 7 Azure migration rules enforced in every commit

---

Test Coverage

8 test suites · 122 tests · 0 failures

Metric	Result	Target
Statements	**88.4%**	80%
Functions	**83.9%**	80%
Lines	**89.3%**	80%
Branches	66.9%	60%

> *Delivered 8–9% above the 80% statement minimum.*

What is tested

Suite	Covers
`auth.test.ts`	Register, login, refresh, logout, delete account, all error paths
`lists.test.ts`	CRUD, ownership enforcement, 401/404 responses
`items.test.ts`	Add, update, delete, toggle checked, reorder
`compare.test.ts`	Full basket comparison, cheaper store logic, edge cases
`split.test.ts`	Split-shop routing algorithm, savings calculation
`products.test.ts`	Search by name, category filter, store price filter

`duplicate.test.ts`	List duplication including all items
`health.test.ts`	DB and Redis cache health endpoint

Tests run against mocked Prisma and Redis — no live database required in CI. Every test uses authenticated requests with the full JWT middleware exercised.

CI/CD Pipeline

```
Push to feature/** or fix/**
        │
        ▼
  ┌──────────────────────────────────────────┐
  │  Job 1: Lint + Test (Jest --coverage)       │
  │  Job 2: Security (npm audit --level=high)    │
  │  Job 3: Docker build validation              │
  └──────────────────────────────────────────┘
        │  All pass?
        ▼
   PR → develop (code review gate)
        │
        ▼
   PR → main
        │
        ▼
   Railway auto-deploy (Sydney)
        │
        ▼
   Live: trolleycheck-pilot-production.up.railway.app
```

Path filters prevent mobile-only UI changes from triggering the API pipeline — Railway deploys are never affected by frontend-only fixes.

What Claude Code Did

Claude Code was used as a senior engineering pair — not a code generator:

- Read the full spec before writing a single line
- Raised GitHub issues before starting each story
- Wrote TypeScript in strict mode — zero `any` escapes
- Wrote tests alongside the implementation, not after
- Caught its own TypeScript errors before committing
- Followed the branching strategy on every story without being reminded
- Debugged CI failures by reading actual error output, not guessing
- Fixed React Navigation architecture issues and mobile keyboard/safe-area bugs
- Enforced Azure migration rules across every file it touched

Every file in this repo was written by Claude Code based on the spec and user prompts — no manual coding.

Pilot Next Steps

Item	Status
EAS Build — shareable APK/IPA	Ready — Expo account needed

Real store price data	Phase 2 — data partnership or scraping
Push notifications — price alerts	Out of scope for pilot
Azure migration	Terraform drafted, 7 migration rules already enforced
App Store / Play Store listing	Requires EAS + developer accounts
Household sharing / collaborative lists	Out of scope for pilot

---

Summary

Metric	Value
Time from spec to deployed app	1 session
Lines of application code	~6,000
API endpoints	25+
Test cases	122
Statement coverage	88.4%
GitHub issues	20
Branches	18
CI pipeline jobs	3 (lint/test, security, Docker)
Stores in app	4 (Coles, Woolworths, IGA, ALDI)
Seed products	90 across 9 categories
Deployment	Railway Sydney — live
